

Programming Assignment Signal and System,

EEL1020

NAME	ROLL NO.
TUSHAR KUMAR	B20AI048
ABHAY PRATAP SINGH	B20CI002

Aim

To get original signal $X[n]$ from a given distorted signal $Y[n]$.

Performing Operations:

1. First remove noise and then sharpen (deblur). Let the resulting signal be $x1[n]$.
2. First sharpen (deblur) and then remove noise. Let the resulting signal be $x2[n]$.
3. Then, compare $x1[n]$ and $x2[n]$ with $[n]$.

Given Kernel : $h[n] = [1/16, 4/16, 6/16, 4/16, 1/16]$

Programming Language Used: Python3

Required Libraries :

- Matplotlib - for plotting the graphs
- Numpy - many operations required
- CSV - for minor uses only

Here,

$$>>Y[n] = X[n]*h[n] + d[n]$$

24 July 2021

$$>> Y2[n] = X[n] * h[n]$$

$$>> F[Y] = F[X] \times F[h]$$

$$>> F[X] = F[Y] / F[h]$$

$$>> X[n] = \text{InvFT}(F[X])$$

Main Idea : Here we are going to use very simple basic concepts learned in this course like 2-D signals, Convolution , Fourier Transform , Inverse Fourier Transform and Sampling etc. to solve this problem.

As we know distorted signal is combination of blurred and noisy signal. In this problem

$$Y[n] = X[n] * h[n] + d[n]$$

Where $h[n]$ is given kernel which has been used for blurring and $d[n]$ is additive noise.

Now clearly we can first denoise the given signal using convolution technique or by averaging the consecutive terms of the signal. For our purpose we'll use averaging here. Then once we have this denoised signal we have to find such signal that gives $Y[n]$ when convolved with $h[n]$.

Clearly it is problem of deconvolution and as we know convolution is just multiplication in frequency domain we'll first calculate Fourier transforms of $Y[n]$ and $h[n]$ and then by dividing them we get corresponding

Fourier transform of $X[n]$. But here we have different dimensions for $Y[n]$ and $h[n]$ and thus we can not directly divide their Fourier transforms so we sample both signals to a certain value and then by dividing both **Fourier transforms** we find **$F[X]$** . Then we can easily find $X[n]$ by using Inverse Fourier transform technique. And thus we get our estimation for original signal.

Then for second part we'll just reverse the order means we'll do deconvolution first and then from that debarred signal we'll do removal of noise.

NOTE: When dividing Fourier transforms $F[Y]$ and $F[h]$ we can face the case where $F[h]$ is nearly zero and therefore we clip the signal to avoid that situation.

Explanation for Theoretical terms:

- **Convolution** : Convolution is a mathematical way of combining two signals to form a third signal. It is the single most important technique in Digital Signal processing.

Formula

$$(f * g)(t) \triangleq \int_{-\infty}^{\infty} f(\tau)g(t - \tau)\tau'$$

$(f * g)(t)$ = functions that are being convoluted

t = real number variable of functions f and g

$g(\tau)$ = convolution of the function $f(t)$

τ' = first derivative of $g(\tau)$ function

- **Fourier transform** : A Fourier transform is a mathematical transform that decomposes functions depending on space or time into functions depending on spatial or temporal frequency, such as the expression of a musical chord in terms of the volumes and frequencies of its constituent notes.

Time Duration		
Finite	Infinite	
Discrete FT (DFT) $X(k) = \sum_{n=0}^{N-1} x(n)e^{-j\omega_k n}$ $k = 0, 1, \dots, N-1$	Discrete Time FT (DTFT) $X(\omega) = \sum_{n=-\infty}^{+\infty} x(n)e^{-j\omega n}$ $\omega \in (-\pi, +\pi)$	discr. time n
Fourier Series (FS) $X(k) = \int_0^P x(t)e^{-j\omega_k t} dt$ $k = -\infty, \dots, +\infty$	Fourier Transform (FT) $X(\omega) = \int_{-\infty}^{+\infty} x(t)e^{-j\omega t} dt$ $\omega \in (-\infty, +\infty)$	cont. time t
discrete freq. k	continuous freq. ω	

- **Inverse Fourier transform** : In this process we basically reverse the doings of Fourier transform.

- Fourier Transform of $x(t)$: $\mathcal{F}[x(t)]$ or $X(\omega)$:

$$X(\omega) = \int_{-\infty}^{\infty} x(t)e^{-j\omega t} dt$$

- Inverse Fourier Transform of $X(\omega)$: $\mathcal{F}^{-1}[X(\omega)]$:

$$x(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} X(\omega)e^{j\omega t} d\omega$$

- **Sampling** : In signal processing, sampling is the reduction of a continuous-time signal to a discrete-time signal. A sample is a value or set of values at a point in time and/or space.

Comparison:

- Sum Square Difference (SSD) of $x1[n]$ with respect to $x[n]$: 144.34195453467495
- Sum Square Difference (SSD) of $x2[n]$ with respect to $x[n]$: 143.41910330051917

Conclusions : After calculations standard square difference of both $X1[n]$ and $X2[n]$ w.r.t $X[n]$, we find that correlation between $X1[n]$ and $X[n]$ is slightly lower. Hence, we conclude that $X2[n]$ is a better estimate of original signal for given distorted signal.

Therefore we can say that the original signal was first blurred and then noise was added to it.

Explanation : Blurring, by default, removes high-frequency information. Thus, the high frequencies of H must go towards zero. The reason for this is that the high-frequency information of X is lost when it is blurred -- thus, the high-frequency components of Y must go towards zero. For that to happen, the high-frequency components of H must also go towards zero. As a result of the high-frequency components of H being almost zero, we see that the high-frequency components of Y is amplified significantly (as we almost divide by zero) when we deconvolve with the FT. This is not a problem in the noise-free case. In the noisy case, however, this is a problem. The reason for this is that noise is, by definition, high-frequency information. So when we try to deconvolve Y , the noise is amplified to an almost infinite extent. Therefore we first try to remove the noise of the signal before we try to deblur that. This is the reason why we get better result in case1.
